REPORT ON THE QUALITY OF MARINE SURFACE OBSERVATIONS: JULY TO DECEMBER 2009

CONTENTS

- 1. Introduction
- 2. Monitoring methods
- 3. Monitoring results:
 - 3.1 Pressure
 - 3.2 *Wind*

(ii)

- 3.3 Sea-surface temperature
- 4. Summary

JULY TO DECEMBER 2009

LIST OF TABLES

- 1. Frequency distribution of the number of observations of pressure, wind and SST.
- 2. Number of observations of pressure for past six-month periods.
- 3. Platforms reporting suspect pressure observations:
 - 3a Stations reporting in DRIFTR code.
 - 3b Stations reporting in SHIP code.
- 4. Platforms reporting in SHIP code, not listed in table 3 but listed as suspect in the previous six-month period.
- 5. Platforms reporting suspect wind speed observations:
 - 5a Stations reporting in DRIFTR code.
 - 5b Stations reporting in SHIP code.
- 6. Platforms reporting in SHIP code,not listed in table 5 but listed as suspect in the previous six-month period.
- 7. Platforms reporting suspect wind direction observations:
 - 7a Stations reporting in DRIFTR code.
 - 7b Stations reporting in SHIP code.
- 8. Platforms reporting in SHIP code, not listed in table 7 but listed as suspect in the previous six-month period.
- 9. Platforms reporting suspect sea surface temperature:
 - 9a Stations reporting in DRIFTR code.
 - 9b Stations reporting in SHIP code.
- 10. Platforms reporting in SHIP code, not listed in table 9 but listed as suspect in the previous six-month period.
- 11. Number of platforms reporting suspect pressure, wind and sst observations for each of the six-month periods covered by the WMO reports on the quality of marine observations.

JULY TO DECEMBER 2009

LIST OF FIGURES

- 1. Number of observations of pressure for past six-month periods.
- 2a Distribution of O-B SHIP pressure differences, all observations.
- 2b Distribution of O-B SHIP pressure differences, flagged observations only.
- 2c Distribution of O-B SHIP pressure differences, unflagged observations only.
- 2d-f As 2a-c but for wind speed.
- 2g-I As 2a-c but for wind direction.
- 2j-l As 2a-c but for SST.
- 3. Geographical distribution of bias of SHIP pressure.
- 4. Geographical distribution of standard deviation of SHIP pressure.
- 5. Geographical distribution of the number of SHIP pressure observations.
- 6-8 As figures 3-5 but for wind speed.
- 9-11 As figures 3-5 but for wind direction.
- 12-14 As figures 3-5 but for SST.

JULY TO DECEMBER 2009

1. INTRODUCTION

In 1985, the WMO Commission for Basic Systems (CBS) agreed that there was a need for GDPS / Global NWP centres to monitor the quality of observations available on the GTS and to exchange monthly lists of stations providing seemingly erroneous data. In 1988 three lead centres were nominated which would have a co-ordinating role of producing, at six-monthly intervals, consolidated lists of suspect stations for given data types together with information on the nature of the error. NCEP was given responsibility for aircraft and satellite data and ECMWF, that for upper-air data. The Met Office was allocated the role as lead centre for marine surface observations which encompass observations from ships, drifting buoys, moored buoys and other fixed marine platforms. This is the 42nd report and covers the period July to December 2009. For each observing platform identified as suspect, values are supplied for the number of observations received at the Met Office, the number of these observations with gross errors, the observations' mean differences from the background values used by the numerical data assimilation system and the standard deviations of these differences.

Following the CBS recommendations, by the end of the 1980s there were four centres active in the monthly exchange of monitoring information; The Met Office, ECMWF, RSMC Tokyo and NCEP. Since then, a number of other centres have also begun to exchange this information and these reports have included data provided by Météo-France as of report number 23. Initially, the only monitoring information exchanged on marine surface observations related to pressure, and the first two WMO reports addressed that parameter alone. Since then, these reports have contained monitoring statistics for wind observations, now being exchanged between centres on a consistent monthly basis. In addition, the report contains monitoring results for sea-surface temperature (SST). Due to changes in the observation processing system and database structure, there was no monitoring of SST data at the Met Office from May 1998 to September 2000. The SST information presented in reports 20 to 23 was therefore compiled, with permission, from the monthly NCEP monitoring data and so is not directly comparable with that presented in other reports. SST monitoring was reinstated at the Met Office from October 2000.

Page 1 Report no. 42

2. MONITORING METHODS

Errors in observations may arise from a number of sources: the instrument may be malfunctioning, figures may be mistaken while being transferred manually, or there may be corruption of data during transmission. Errors can also arise in the pressure report if the adjustment to sea level is made incorrectly or not at all, and a poorly sighted anemometer can result in errors in the observations of wind. For SST observations, the depth at which the observation is made can be crucial. 'Surface' observations from buoys are usually made at a depth of around 0.5m, whereas ships may take a measurement between a depth of 10m and the surface, depending on the method used. At present, there is no indication given within the report of the observation's depth, so it is not possible to determine the significance of this factor. (By contrast, satellites measure the temperature of the ocean's 'skin' which is generally slightly cooler than the temperature immediately beneath, by several tenths of a °C, as a result of evaporative cooling and other surface processes.)

Some errors can be detected by applying checks on the code format and the internal consistency of the report (for example: are the position and pressure consistent with a report 6 hours earlier?). Checks on spatial consistency are possible where there are other nearby observations. However, such quality checks are unable to identify errors on all occasions and it is recognised that the numerical data assimilation systems in use today can provide global reference values applicable in observation monitoring. The short-term forecast from the previous numerical analysis, commonly known as the first-guess or background field, provides perhaps the most useful information on observation quality, as it represents an accurate and spatially consistent estimate of the observed value which is independent of the observation itself. Observation-minus-background (hereafter referred to as O-B) differences are at the core of all monitoring work by GDPS centres. Due to the thermal-inertia of the oceans and the slowly varying nature of SST, the background SST is in fact the previous analysis (daily analyses are produced at the Met Office from an assimilation of both surface and satellite observations).

Taking all marine surface observations together, the values of O-B have distinct characteristics. The vast majority of the observations show quite small departures from background and the distribution of O-B is nearly Gaussian, with little or no bias. These O-B differences are generally made up from random errors in the background fields and/or the observations, which are statistically of similar magnitude. However, there is a smaller group of observations that depart much more from the background, for which observation error is the only reasonable explanation for the large values of O-B. Studies of the distribution and variation of O-B at different points around the globe enable reasonably accurate estimation of background error, and this provides the basis for the monitoring methods described here. Those marine observing platforms for which, in a sufficiently large sample, the observed values differ from the background by an amount significantly in excess of the estimate of background error, may be labelled as 'suspect' with a high degree of confidence. The limits used here to identify suspect observing platforms have been set appropriately to preclude much likelihood of the background, rather than the observations, being in error.

Each monitoring centre produces a monthly list of the identifiers of marine observing platforms considered suspect according to their departures from the model background values. All observations are used, both synoptic and asynoptic, and the background fields are interpolated to the observation time.

Given that the number of observations made during the month is at least 20, then the condition used by all centres for obtaining platforms for the suspect lists is that at least one of the following criteria are satisfied:

Pressure

1.	mean of O-B	≥4.0 hPa
2.	standard deviation of O-B	≥6.0 hPa
3.	percentage of gross errors	≥25

Wind

1.	mean of O-B	\geq 5.0 ms ⁻¹	(Speed)
		≥30°	(Direction)
2.	standard deviation of O-B	≥80°	(Direction)
3.	percentage of gross errors	≥25	

Criteria used for monthly monitoring

Gross errors are defined as observations that depart from the background by more than 15hPa (Pressure) or 25ms⁻¹ (Vector Wind). The mean and standard deviation of the samples are evaluated excluding gross errors, so that occasional extreme values resulting from, for example, corruption during transmission, do not influence the sample characteristics. Direction statistics are also calculated excluding values in light winds, where either the observed or background speeds are less than 5ms⁻¹.

The monthly results for pressure from all five monitoring centres show considerable agreement, both on the observing platforms listed as suspect and the values of the mean and rms difference from each centre's background. Differences between the monthly suspect lists are usually due to the different numbers of observations available at each centre, due to different cut-off times. There are also some unexplained variations in the data receipt between the centres, which may be due to problems on the GTS or in the local procedures for handling the data. Monitoring results for wind speed also show reasonable agreement on the mean and standard deviation from each centre's background.

This report draws together all the monthly monitoring results exchanged on marine surface data and identifies a list of observing platforms that have provided observations of poor quality over the 6-month period. In drawing up this list, there have been a number of guiding principles:

- 1. As with the monthly lists, accuracy is assessed relative to background values.
- 2. Observing platforms are listed only where there is a reasonable degree of confidence that the observations rather than the background values are in error.
- 3. At least 40 reports are required over the period in which the observations are considered suspect.
- 4. The perceived accuracy over the last part of the six-month period is of greatest importance; observing platforms are not listed if there has been recent improvement and their reports are at present without major error.
- 5. Given that the number of observations made during the period is greater than or equal to 40, then the condition for listing a platform as suspect in this report is that at least one of the following criteria are satisfied:

Pressure

1.	mean of O-B	≥3.5 hPa
2.	standard deviation of O-B	≥5.0 hPa
3.	percentage of gross errors	>25

Wind

1.	mean of O-B	\geq 5.0ms ⁻¹	(Speed)
			(Direction)
2.	standard deviation of O-B	\geq 6.0ms ⁻¹	(Speed)
		≥60°	(Direction)

3. percentage of gross errors ≥ 25

SST

1.	mean of O-B	≥3.0 °C
2.	standard deviation of O-B	≥5.0 °C
3.	percentage of gross errors	≥25

Criteria used for biannual monitoring

All observations having gross errors are excluded from the calculation of the mean and standard deviation of O-B. The same gross error limits apply in these reports as in the monthly lists. The Met Office now sets a limit of 10°C for SST but this was previously 5°C and NCEP use 15°C. Also, criteria used in early reports were based on O-A statistics. Consequently, data presented here is not directly comparable with that in older reports.

The limits on the bias and standard deviation of O-B are more stringent than those for the monthly lists because the sample sizes are larger. If there has been a recent change in quality, they are only applied at the end of the period. Identifiers can be listed in this report without appearing on any of the monthly lists. This is due to a representative sample only being obtained over several months or deterioration occurring at the end of the period for platforms reporting very frequently. The 6-month list is longer than most of the monthly lists because many ships cease reporting for variable periods of time, in many cases while they are in port or out of service. Only over a relatively long period, probably more than 6 months, is a representative sample obtained from all those ships providing observations.

3. MONITORING RESULTS

The monitoring results presented in this report relate only to data exchanged over the GTS. Observations from marine platforms are transmitted in one of two formats: the SHIP code, used for most observations from ships, moored buoys and other fixed platforms, and the BUOY code, used mostly for observations from drifting buoys. In this report, the term "ship observations" refers to those received in the SHIP code and the "drifting buoy observations" to those received in BUOY code. The SHIP code indicates whether the observation was made manually or by an automatic system and accordingly the sub-divisions "manual ship" and "automatic ship" will be defined.

3.1 Pressure

In the six-month period, July to December 2009, 4307461 observations of pressure were monitored at Exeter from 2577 manual ships, 859 drifting buoys, and 495 automatic ships. The number of reports received from individual ships varies greatly as Table 1 demonstrates: a large percentage of ships continue to report only once, which may be due to erroneous call signs, caused by errors in the part of the message giving the ship identifier. A comparison with the corresponding table in report number 41 shows little change. Since most marine observations are located in the northern hemisphere, there is inevitably some seasonal variation in the number of vessels reporting, especially in the case of buoys, since new or replacement buoys are generally deployed in better weather conditions. Considering the general trends over previous reports, the decline in the number of manual ships seems to have stopped, with a small increase, and the recent large decrease in automatic ships has also stopped, but there has been a drop in the number of buoys reporting.

Table 2 and Figure 1 show the number of observations of pressure that have been received over the GTS at the Met Office (and processed) over past 6-month periods. It can be seen that the total number of observations remained fairly steady with only minor fluctuations until report number 11 (January-June 1994). Since that time however, there has been a steady increase in the total up to 2008, with the number of observations of pressure nearly doubling between reports 11 and 16 (1994-1996) and doubling again between reports 33 and 38 (2005-2007). The first increase was largely due to the increase in number of drifting buoy reports, due to the larger number of reports from each drifting buoy. The second increase was due to increased numbers of both drifting buoys and automatic ships, with the number of reports from manual ships remaining fairly constant over recent years, despite the slow reduction in the number of manual ships reporting pressure. The number of reports from drifting buoys seems to have peaked in the second half of 2008 and has decreased slightly over the last two reports; while the number of observations from automatic ships has increased again, after a decline in numbers in the first half of 2009. Reports from drifting buoys now account for 57.4% of the total, while those from manual ships make up just 10.5% of the total, and those from automatic ships account for the remaining 32.1%. The sudden increase seen in the number of automatic ships in report number 19 (January-June 1998) was due to observation processing changes at the Met Office, whereby all reports from 'automatic ships' began to be processed, rather than only one report per 6-hour assimilation period, as previously. Since then there has been a fairly steady increase in the total number of pressure reports, which has only recently levelled-off.

A histogram of O-B differences for all ship pressure reports in the period July to December 2009 is shown in Figure 2a, together with the Gaussian distribution with the same mean and standard deviation. Although almost all values fall within the range +5 to -5 hPa, a small number of much larger values, presumably resulting from erroneous observations, contribute to the large standard deviation of the population. The distribution for all those observations which fail the automatic quality-control checks is broad (Figure 2b). The remaining 93.9% of the observations that pass the quality checks show a distribution of O-B which is very close to Gaussian (Figure 2c) with mean O-B of -0.1hPa and standard deviation of 1.3hPa. The principal contribution to the standard deviation is assumed to be from background errors.

Page 5 Report no. 42

A global estimate of the background error, such as that provided above, can conceal large spatial variations. Background values will be more accurate in data-rich areas (e.g. in the North Sea or Mediterranean) or where the meteorological variability is low (e.g. the tropics). Figures 3 and 4 show the geographical distributions of the mean and standard deviation of the values of O-B from ship observations that passed the quality control checks, calculated for 10-degree latitude-longitude boxes. In most areas the magnitude of the mean is less than 1.0 hPa, the exceptions being generally where the sample size is small. The standard deviation is generally in the range 1.0 to 1.5 hPa, but is less than 1.0 hPa in some areas of the north Atlantic, the north-west Pacific and the tropics. The number of ship pressure reports that passed the quality control checks are shown in Figure 5.

Table 3 contains a list of those ships and drifting buoys considered to have produced suspect observations of pressure in the period July to December 2009. Values over the six-month period are given for the number of observations of pressure available for Met Office global model runs, the number of observations differing from the model background value by more than 15 hPa (gross errors), and the mean and standard deviation of the model O-B. The number of times the identifier has appeared on the monthly suspect lists from the five monitoring centres is also given. In order to give a detailed picture of the frequency of reporting and any changes in the observation accuracy, 6-month time-series of O-B differences are given at the end of the report for each of the identifiers listed.

An interesting characteristic of the errors identified here, which soon becomes obvious on inspection of the time-series charts at the end of this report, is that most can be attributed to a bias in the observed pressure. In many cases, the bias is constant over the whole monitoring period; although some values depart greatly from the sample mean, presumably due to some gross error in the observation, these are generally isolated instances. In only a few cases are there regular large random departures from background. Those observing platforms listed in Table 3 which appeared in report number 41 (January to June 2009) have been indicated with an asterisk. A comparison of the statistics given here with those in the report number 40 (July to December 2008), clearly indicates that the bias in the pressure observations from a few ships has hardly changed for more than a year.

Statistics for those marine observing platforms listed in report number 41 and which do not appear in Table 3b, are given in Table 4 along with comments on the quality of their pressure observations. Time-series of the pressure observations from these platforms are not given. Less than 40 reports were received in the 6-month period for many of these platforms, but 62% of platforms on the list do show some improvement in the quality of their observations.

3.2 Wind

Monitoring observations of wind is more problematical than pressure. On most observing platforms, wind is measured using anemometers; the reported speed depends upon the averaging period and instrument height above sea level, which varies a great deal between platforms. Since large structures distort wind flow, the anemometer position relative to the wind bearing and platform structure does affect the measurement. (These factors do not apply to those ship observations where wind speed is based on visual estimates of the sea state e.g. the UK VOS fleet.)

In these monitoring results, the background winds are valid at a height of 10 metres above mean sea level; rather lower than the average height of ship anemometers. Where anemometer height is much different from 10 metres, a significant O-B speed bias may be evident. Examples of this are (i) observations from oil rigs or tankers with anemometer heights of 50m or more, although the speeds reported by most rigs are now adjusted on board to be nominal 10m values, and (ii) buoys, where the anemometer can be as low as 2m.

In the period July to December 2009, 1921040 wind observations were available for monitoring at Exeter, from 2598 manual ships, 40 drifting buoys, and 538 automatic ships. (More detail is given in Table 1.) The number of reported manual ship identifiers shows the same trends as for pressure, but with slightly more identifiers reporting wind. As stated for pressure observations, the large increase in the number of monitored wind observations seen in report 19 was largely due to the inclusion of all 'automatic ship' data, instead of just one report in each six hour period.

Histograms of O-B differences for ship observations of wind speed are presented in Figures 2d, 2e and 2f and of wind direction in Figures 2g, 2h and 2i. As with observations of pressure, those wind observations that fail the quality-control checks differ most from background, some by as much as 50 ms⁻¹, and they make a large contribution to the variance of O-B. The distributions of O-B wind speed and direction for the remaining 93% of the observations are nearly Gaussian. There is a speed bias of 1.1 ms⁻¹ relative to background, with a direction bias of just -0.8°.

Figures 6 and 7 show the geographical distributions over the six-month period of the mean and standard deviation of O-B for ship observations of wind speed that pass the quality-control checks. The numbers of wind reports used to generate these statistics are presented in Figure 8. The standard deviation of O-B wind speed is typically 2-3 ms⁻¹ in middle latitudes and around 1.5 ms⁻¹ in the tropics. The bias is generally around +1 ms⁻¹, but exceeds +2 ms⁻¹ in a few places, whereas it is slightly negative to the north of the UK and in some tropical areas. Similar distributions of the mean and standard deviation of O-B wind direction are shown in Figures 9 and 10. Only reports where both the observed and background wind speeds are greater than 5 ms⁻¹ were used to obtain these values. The magnitude of the bias is less than 5 degrees in most places, but is up to 15 degrees in a few places in the tropics. The standard deviation is generally between 20 and 30 degrees globally, but in some data-sparse areas and near some coasts it is as large as 40-50 degrees. The numbers of reports of wind direction used to generate these statistics are presented in Figure 11.

Figures 6-11 provide reference values against which to compare the O-B characteristics for different marine observing platforms. Table 5 contains a list of those ships and drifting buoys considered to have produced suspect observations of wind speed in the period July to December 2009, and in Table 7 a similar list is provided for wind direction. Values are given for the number of observations of wind received at the Met Office, the number of observations having a vector difference from background of more than 25ms⁻¹ (gross errors), and the mean and standard deviation of O-B. Time-series of O-B are given at the end of the report for each listed identifier. In the majority of the cases of suspect speed observations, a constant bias is clearly evident. Errors in observations of direction are more random in nature. Tables 6 and 8 contain statistics for platforms reporting in ship code which are not included in Tables 5 and 7 but that were listed in the previous report, for wind speed and direction respectively. Time-series for these identifiers are not included in this report.

3.3 Sea-surface temperature

In the 6-month period July to December 2009, a total of 6816958 observations of SST were monitored at the Met Office, from 2230 manual ships, 1893 drifting buoys and 351 automatic ships. Of the total, 394531 were from manual ships, 5304003 from drifting buoys and 1118424 from automatic ships. (More detail is given in Table 1.) For the same reasons as stated for pressure observations, it appears that many identifiers report only once during the 6-month period. There has been little change in the numbers of ships and drifters reporting SST over the last 4 years, although the number of buoys has increased by 7% for this reporting period and the number of manual ships has gone down by 7%. There are similar numbers of manual ships reporting SST as there are drifting buoys and automatic ships combined, but manual ships account for only 6% of the total number of observations. This is due to the greater frequency of automatic ship and buoy observations, hourly in many cases, with manual ships tending to report only at the main synoptic hours.

Histograms of O-B differences for all ship SST reports are shown in Figures 2j, 2k and 2l. As with observations of pressure and wind, those SST observations that fail the quality-control checks differ most from background and make a large contribution to the variance of O-B. The distribution of O-B SST for the remaining 87% of the observations is nearly Gaussian, with a standard deviation of 1.1°C and no bias relative to the background.

Figures 12 and 13 show the geographical distributions over the 6-month period of the mean and standard deviation of O-B for ship observations that passed the quality control checks. The numbers of reports used to generate these statistics are presented in Figure 14. The bias is generally less than 0.5°C and the standard deviation is around 1°C.

Table 9 contains a list of the ships and drifting buoys considered to have produced suspect observations over the 6-month period. The comments given in each case provide an indication of the main reason for the station to be listed as suspect; time-series charts have also been plotted for SST and are included at the end of the report. The majority of the identifiers appearing on the list do so because of bias. Table 10 gives details of the performance over the latest 6-month period of ships which were considered suspect in the previous period but which do not appear in Table 9.

4. SUMMARY

There are 79 marine observing platforms listed as producing suspect observations of pressure over the period July to December 2009, 88 as producing suspect wind observations and 60 as producing suspect SST observations. The first report issued by RSMC Bracknell, for the period January to June 1989, listed 150 marine platforms producing suspect observations of pressure. With the selection criteria remaining unchanged, an initial reduction in the number of platforms listed as suspect was followed by a series of reports listing similar numbers of suspects, around 80. There was an increase in suspect numbers during 1999 and 2000 and since then the numbers have fluctuated, mostly between 100 and 160, although over the past two years there has been a downward trend, with a decrease of 35% over the previous year. Considering the fluctuations in numbers of platforms reporting and observations monitored, there seems to be little overall trend in observation quality.

For wind observations, over the years up to 2002 there was a tendency for a small increase in the number of wind observing platforms listed as suspect, but since then the numbers have fluctuated, mostly between 100 and 150, except for the last two report periods which have been well below 100. The number of SST observing platforms listed as being suspect has been fairly constant over the last two years, following a decrease in numbers from a high value of 225 four years ago.

The most common characteristic in the case of identifiers listed as producing suspect pressure observations is bias in the reported pressure, sometimes remaining constant for many months. In the case of wind suspects, the most common reason for listing a platform is either a bias in the reported wind speed or a large standard deviation in wind direction, with fewer having a bias in wind direction. For sea-surface temperature observations, bias is again the most common cause of error.

The selection criteria have been set appropriately to ensure that the platforms listed are only those for which there is a high degree of confidence in their reports having errors. There are many others, not listed here, for which there must be considerable doubt over the quality of the observations. A wider range of monitoring results is available from the Met Office on request.

TABLE 3: LIST OF MARINE OBSERVING PLATFORMS REPORTING SUSPECT PRESSURE OBSERVATIONS OVER THE PERIOD JULY TO DECEMBER 2009.

Column 1 Call sign or identifier.

Column 2 Number of pressure observations available for monitoring over the 6-month period, excluding duplicates, but including any observations with gross errors.

Column 3 Number of pressure observations differing by more than 15 hPa from background (gross error).

Column 4 Standard deviation of observation-minus-background differences excluding cases of gross error.

Column 5 Mean of observation-minus-background differences (bias) excluding cases of gross error.

Columns 6-10 Number of times observing platform has appeared on suspect lists. B=Exeter, E=ECMWF, F=MétéoFrance, T=Tokyo, W=Washington.

Column 11 Comments on quality of pressure observations.

Notes: 1. Units are hPa.

2. Observing platforms marked with an asterisk were listed in the previous report January to June 2009)

Table 3a: Platforms reporting in BUOY code

i): Platforms non-operational at the end of the reporting period

TABLE 5: LIST OF MARINE OBSERVING PLATFORMS REPORTING SUSPECT WIND SPEED OBSERVATIONS OVER THE PERIOD JULY TO DECEMBER 2009.

Column 1 Call sign or identifier. Column Number of wind speed observations available for monitoring over the 6-month period, excluding duplicates, but including any observations with gross errors. Number of wind observations with vector difference from Column 3 background of more than 25ms⁻¹ (gross error). Column 4 Standard deviation of observation-minus-background differences excluding cases of gross error. Column 5 Mean of observation-minus-background differences (bias) excluding cases of gross error.

Column 6-10 Number of times observing platform has appeared on suspect lists.

B=Exeter, E=ECMWF, F=MétéoFrance, T=Tokyo, W=Washington.

Column 11 Comments on quality of wind speed observations.

Notes: 1. Units are ms⁻¹

2. Observing platforms marked with an asterisk were listed in the previous report (January to June 2009)

Table 5a: Platforms reporting in BUOY code

i): Platforms non-operational at the end of the reporting period

TABLE 7: LIST OF MARINE OBSERVING PLATFORMS PRODUCING SUSPECT WIND DIRECTION OBSERVATIONS OVER THE PERIOD JULY TO DECEMBER 2009.

Column 1 Call sign or identifier.

Column 2 Number of wind direction observations available for monitoring over the 6-month period, excluding duplicates, but including any observations with gross errors.

Column 3 Number of wind observations with vector difference from background of more than 25ms⁻¹ (gross error).

Column 4 Standard deviation of observation-minus-background differences excluding cases of gross error.

Column 5 Mean of observation-minus-background differences (bias) excluding cases of gross error.

Column 6-10 Number of times observing platform has appeared on suspect lists. B=Exeter, E=ECMWF, F=MétéoFrance, T=Tokyo, W=Washington.

Column 11 Comments on quality of wind direction observations.

Notes: 1. Units are degrees (°).

- 2. Observing platforms marked § had a significant speed bias at some time within the period and the statistics and their plots refer to direction reports associated with background wind speeds greater than 5 ms⁻¹. If no significant speed bias was present, the statistics and plots refer to direction reports with an observed speed greater than 5 ms⁻¹.
- 3. Observing platforms marked with an asterisk were listed in the previous report (January to June 2009)

Period of data: JUL-DEC 2009 Data used: Flagged observations

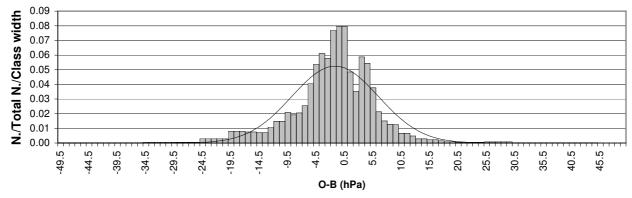

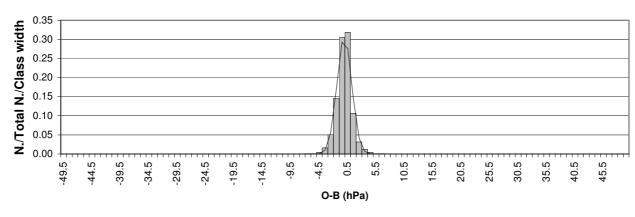

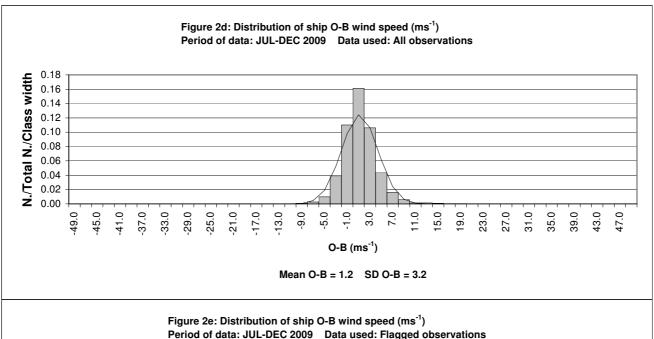

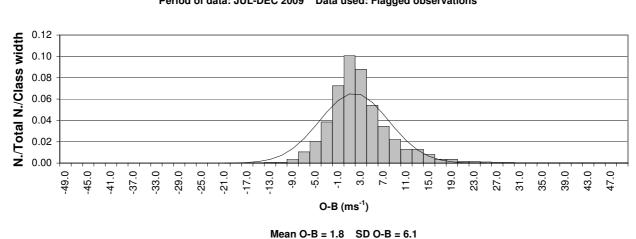

Figure 2c: Distribution of ship O-B pressure (hPa)
Period of data: JUL-DEC 2009 Data used: Unflagged observations

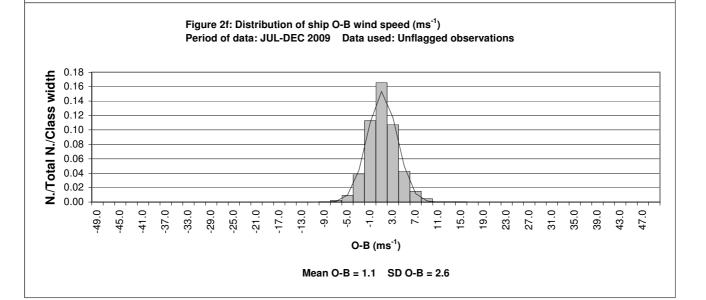

Mean O-B = -1.2 SD O-B = 7.6

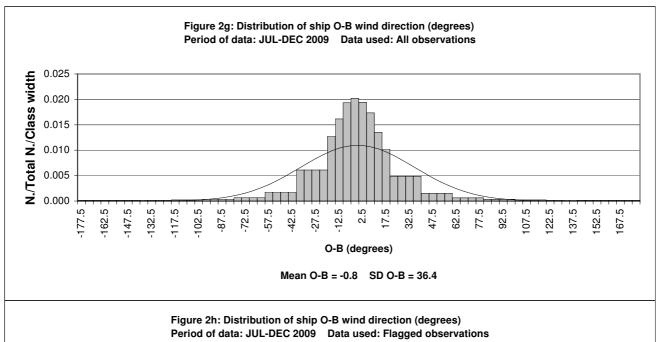

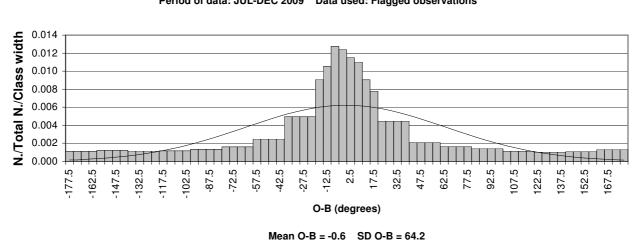

Mean O-B = -0.1 SD O-B = 1.3

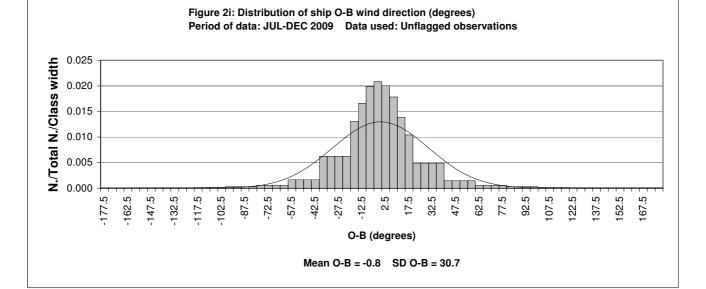

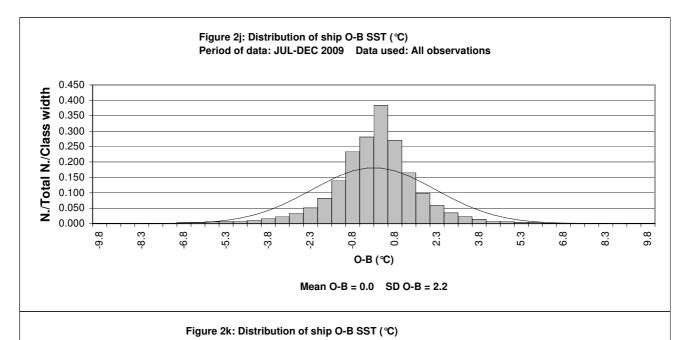

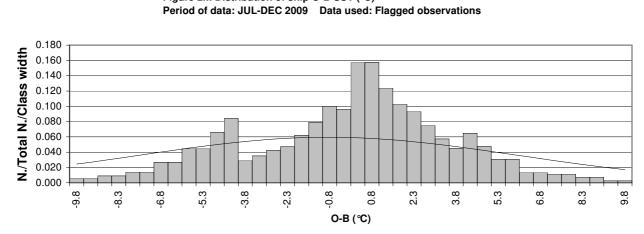

Mean O-B = -0.8 SD O-B = 6.7

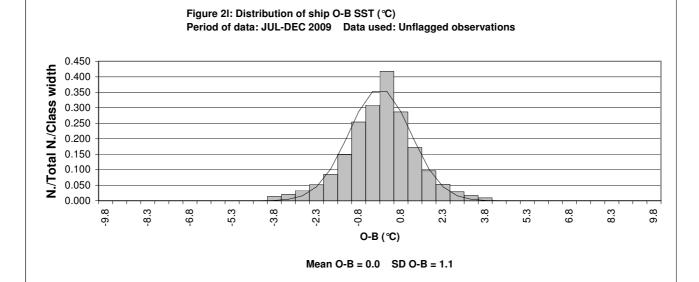

Figure 3: Bias of Ship O-B Pressure (hPa). Date:- July - December 2009
Only observations passing quality control used in statistics
Contours drawn to 10 degree boxes, if the number of observations is greater than 10
Shaded areas have a bias of magnitude greater than 1.0 hPa

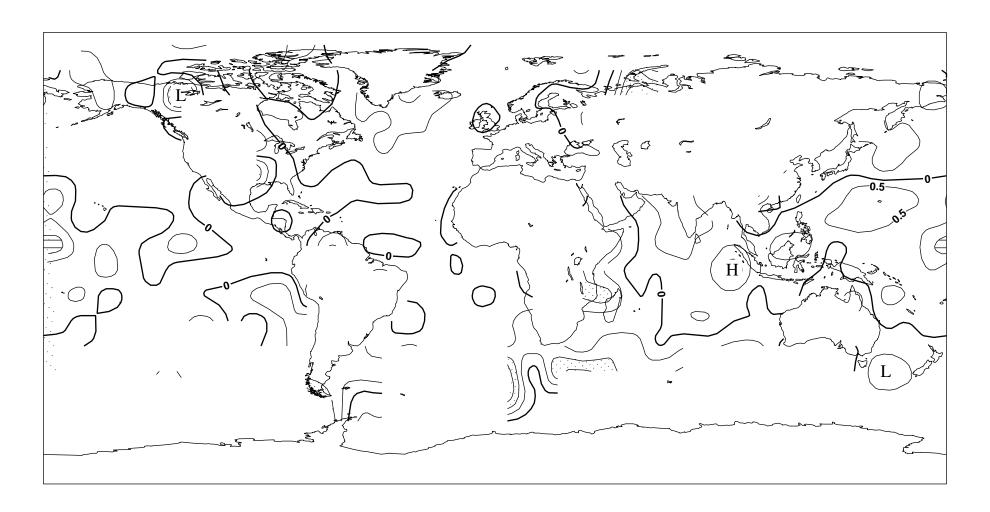

Figure 4: Standard Deviation of Ship O-B Pressure (hPa). Date:- July - December 2009 Only Observations passing quality control used in statistics Contours drawn to 10 degree boxes, if the number of observations is greater than 10 Shaded areas have a standard deviation of greater than 2.0 hPa

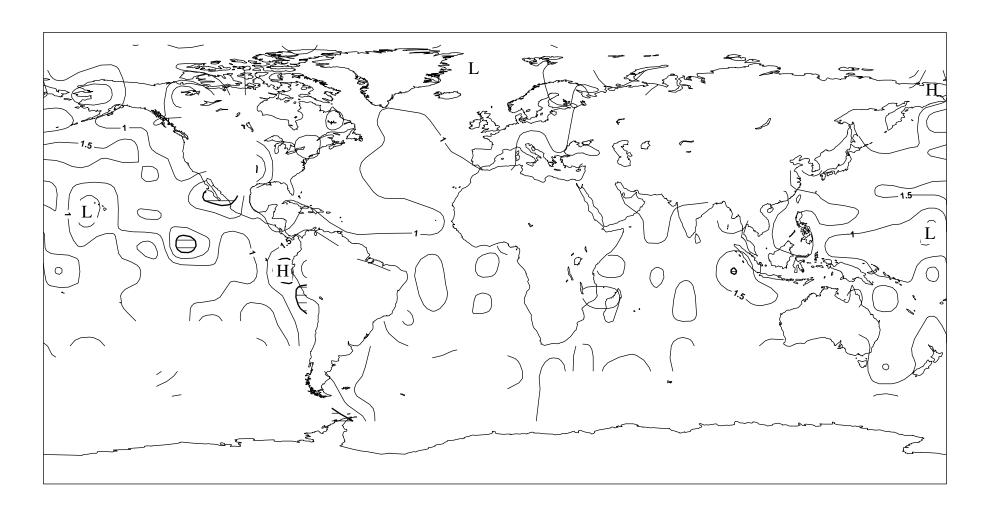

Figure 5: Plot of the Number of Ship Pressure Observations. Date:- July - December 2009 Only observations passing quality control included

Figure 12: Bias of Ship O-B SST (degrees C). Date:- July - December 2009
Only observations passing quality control used in statistics
Contours drawn to 10 degree boxes, if the number of observations is greater than 10
Shaded areas have a bias of magnitude greater than 1.0 degree C

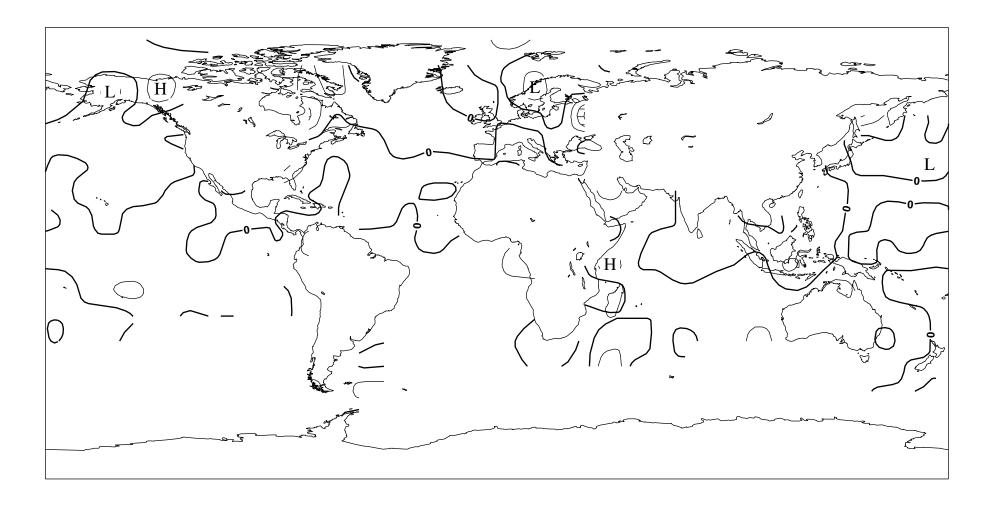

Figure 13: Standard Deviation of Ship O-B SST (degrees C). Date:- July - December 2009 Only Observations passing quality control used in statistics Contours drawn to 10 degree boxes, if the number of observations is greater than 10 Shaded areas have a standard deviation of greater than 2.0 degrees C

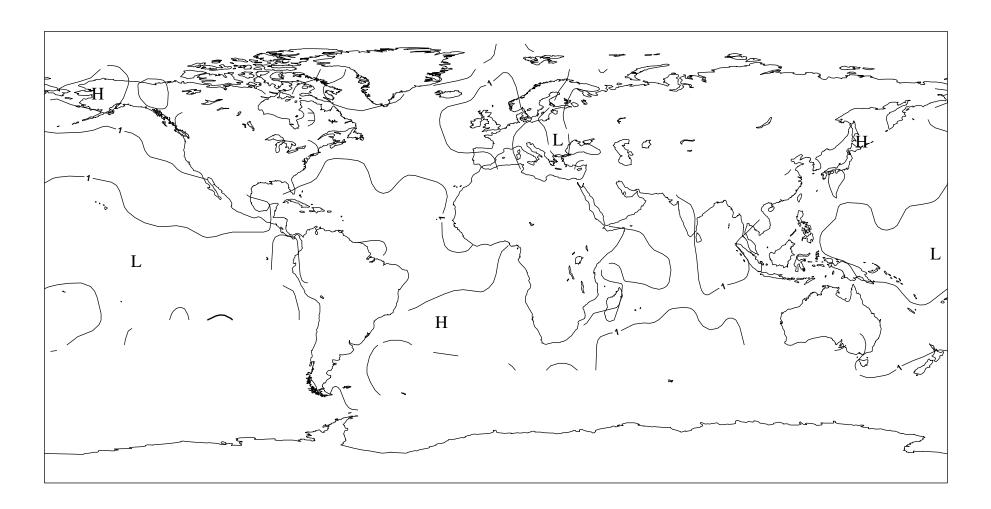

Figure 14: Plot of the Number of Ship SST Observations. Date:- July - December 2009 Only observations passing quality control included
