Introduction

The Bureau of the Meteorological Station of Vigna di Valle (Site of the R.S.M.A. - Italian Air Force) has been awarded the "atmospheric wet-deposition collection", of which one starting from 1993 and dedicated to the collection of meteoric precipitation samples and its characterization from 2002 to collect daily precipitation samples. In the same Center is running a chemical monitoring program on the effects of pluvial sediments on meteoric precipitation, within international collaboration of the IAPSO (International Organization of Hydrology) (1990) and the UN (1996). Monitoring Meteoric, started from 1975 and till the UN (1996), has the main goals to monitor quantification of content and trends in the composition of atmospheric precipitation at global and regional scale, to facilitate global assessments of acid-deposition and to integrate historical data from more recent data and to provide the influence of acid deposition on soil degradation and for different ecosystems. To accomplish such activity, from July 2001 to July 2002, a detailed period of experimentation is begun in order to evaluate the seasonal dependence of sampling and to measure the difference found in terms of acidity and other chemical parameters and to assess the impact of precipitation on the environment.

Annual rain is slightly acidic, with a pH of around 4. This is due to a mixture of sulfuric (sulfur dioxide (SO₂)) and nitric (nitrogen dioxide (NO₂)) acids, associated with the degree of the air pollution.

$$SO_2 + H_2O \rightarrow H_2SO_3 \approx 1000 \times 10^{-14}$$

On the other pH level, it is known that the pH of the rain is influenced by the presence of sulfuric acid.

Research activity carries on the use of fixed sites for energy research, in the vicinity of sulfur dioxide (SO₂), and sulfuric (H₂SO₄) and the interaction. This process must be measured in laboratory before coming back down to earth in the form of precipitation and precipitation.

Dissociation of the atmosphere, SO₂, and H₂SO₄, reacts with water impurities to form weak solutions of sulfuric and sulfuric acid.

$$H_2SO_3 + H_2O \rightarrow H_2SO_4$$

$$SO_2 + H_2O \rightarrow H_2SO_3$$

Sample collection, storage and analytical procedures

Site details Sampling is carried out in the meteorological station of Vigna di Valle (Center, Km 47 km S. Lungro 177), which is located in the center of the town of Vigna di Valle, in the Province of Rome, in all directions and kilometers from a highly industrialized and densely populated area (20 Km).

The site (E 122, N 41° 57' 00") is located in the center of the town, approximately 100 meters away from the small difference in altitude, the highest point of the town.

Water sample collection Samples are taken every 10 minutes during 1000-1010 hours daily sampling time (at 1000 hours local time of the month). Rain has been collected in a closed container, which is placed in a closed container, to reduce the possibility of contamination of the sample. The sample is collected in a closed container, to reduce the possibility of contamination of the sample.

Storage and handling Samples are stored in a closed container, which is placed in a closed container, to reduce the possibility of contamination of the sample. Samples are stored in a closed container, to reduce the possibility of contamination of the sample. Samples are stored in a closed container, to reduce the possibility of contamination of the sample.

Measurement instruments Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Laboratory analysis Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Quality assurance Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Data processing Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Statistical analysis Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Results Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Methodology Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Instrument calibration Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Method validation Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Method reproducibility Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Method precision Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Method detection limit Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Method detection limit Measurements are made using a digital pH meter, which is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions. The pH meter is calibrated with standard buffer solutions.

Results

Conclusions

In this work, the seasonal variability and relative state of air over a period of experimentation (based on July 2000 at the meteorological station of Vigna di Valle) are shown. They're linked to comparison of analysis of chemical data carried out by meteoric precipitation samples, collected weekly and daily. When the experiments will be concluded, this work would have to carry to overlap the two sampling data and to distribute every event that have been done with "pH effect" and, at the same time, to be able to measure these phenomena of a meteorological specific situation.

This study comes from the opportunity of having in the same air two complete controlled constantly: the chemical laboratory is responsible of collected samples analysis, of successive data analytical validation and statistic elaboration.

All that is inserted in the notion of atmospheric pollution monitoring, acidity and therefore also of acid rain control and by "GATT", which the A.M. is member of since 1973, managing a set of collection stations, that also comprise the site of Vigna di Valle (from 1986). Finally, through pH diagrams and other chemical-physical parameters, it's possible to represent a first information emerged from the analysis of two different kind of discharge collected, and also it's possible make a valuation about differences and future perspectives of this experimentation.
